150,000 ROOMS BOOKED IN AIRBNB

Situated on some of the Hotel's topmost floors, contemporary-style, one-bedroom Deluxe Suites in Four Seasons Hotel Mumbai offers superb views of the Arabian Sea from floor-toceiling windows.

Elegant Décor

Calming color schemes of green and beige, paneled walls and mahogany and maple wood furnishings create a warm atmosphere, while rich silk and mohair accessories lend an exotic feel.

The Height of Comfort

· Your accommodating living area is furnished with a comfortable sofa and chaise longue.

- 140-centimetre (55-inch) 3D television
- Coffee/tea maker and private bar
- Complimentary wired and wireless Premium Internet access to specialty suites guests. Up to two devices.

Spacious Bathroom

 Overlooking the sea, your marble bathroom features a double vanity, deep soaking tub, glass-enclosed rain shower and separate WC. A guest powder room is located off the living area.

Enjoy views of the Arabian Sea and abundant natural light from the floor-to-ceiling windows in these large rooms in Four Seasons Hotel Mumbai.

Room Details

BEDS	King or two twin beds
OCCUPANCY	3 adults, or 2 adults and 1 child
EXTRA BED	One rollaway and one crib
LOCATION	7th to 32nd floor
VIEW	Arabian Sea
SIZE	49 m2 (527 sq.ft.)
BATHROOMS	One full marble bathroom

WHAT IS BLOCKCHAIN?

"Open, distributed ledger that can record transactions between two parties efficiently and in a verifiable and permanent way"

WHAT IS BLOCKCHAIN?

OPEN

DISTRIBUTED

LEDGER

P2P

PERMANENT

Someone requests a transaction.

The transaction

is complete!

The requested transaction is broadcast to a P2P network consisting of computers known as nodes.

The P2P network of nodes validates the transaction and the user's status using known algorithms.

The new block is then added to the existing blockchain in a way that is permanent and unalterable. Once verified, the transaction is combined with other transactions to create a new block of data for the ledger. A verified transaction can involve cryptocurrency, contracts, records, or other information.

Has no intrinsic value in that it is not redeemable for another commodity.

> Has no physical form and exists only in the network.

Its supply is not determined by a central bank, and the network is completely decentralized.

Bitcoin: A Peer-to-Peer Electronic Cash System

Satoshi Nakamoto satoshin@gmx.com www.bitcoin.org

Abstract. A purely peer-to-peer version of electronic cash would allow online payments to be sent directly from one party to another without going through a financial institution. Digital signatures provide part of the solution, but the main benefits are lost if a trusted third party is still required to prevent double-spending. We propose a solution to the double-spending problem using a peer-to-peer network. The network timestamps transactions by hashing them into an ongoing chain of hash-based proof-of-work, forming a record that cannot be changed without redoing the proof-of-work. The longest chain not only serves as proof of the sequence of events witnessed, but proof that it came from the largest pool of CPU power. As long as a majority of CPU power is controlled by nodes that are not cooperating to attack the network, they'll generate the longest chain and outpace attackers. The network itself requires minimal structure. Messages are broadcast on a best effort basis, and nodes can leave and rejoin the network at will, accepting the longest proof-of-work chain as proof of what happened while they were gone.

1. Introduction

Commerce on the Internet has come to rely almost exclusively on financial institutions serving as trusted third parties to process electronic payments. While the system works well enough for most transactions, it still suffers from the inherent weaknesses of the trust based model. Completely non-reversible transactions are not really possible, since financial institutions cannot avoid mediating disputes. The cost of mediation increases transaction costs, limiting the minimum practical transaction size and cutting off the possibility for small casual transactions, and there is a broader cost in the loss of ability to make non-reversible payments for non- reversible services. With the possibility of reversal, the need for trust spreads. Merchants must be wary of their customers, hassling them for more information than they would otherwise need. A certain percentage of fraud is accepted as unavoidable. These costs and payment uncertainties can be avoided in person by using physical currency, but no mechanism exists to make payments over a communications channel without a trusted party.

What is needed is an electronic payment system based on cryptographic proof instead of trust, allowing any two willing parties to transact directly with each other without the need for a trusted third party. Transactions that are computationally impractical to reverse would protect sellers from fraud, and routine escrow mechanisms could easily be implemented to protect buyers. In this paper, we propose a solution to the double-spending problem using a peer-to-peer distributed timestamp server to generate computational proof of the chronological order of transactions. The system is secure as long as honest nodes collectively control more CPU power than any cooperating group of attacker nodes.

2. Transactions

We define an electronic coin as a chain of digital signatures. Each owner transfers the coin to the next by digitally signing a hash of the previous transaction and the public key of the next owner and adding these to the end of the coin. A payee can verify the signatures to verify the chain of ownership.

The problem of course is the payee can't verify that one of the owners did not double-spend the coin. A common solution is to introduce a trusted central authority, or mint, that checks every transaction for double spending. After each transaction, the coin must be returned to the mint to issue a new coin, and only coins issued directly from the mint are trusted not to be double-spent. The problem with this solution is that the fate of the entire money system depends on the company running the mint, with every transaction having to go through them, just like a bank.

We need a way for the payee to know that the previous owners did not sign any earlier transactions. For our purposes, the earliest transaction is the one that counts, so we don't care about later attempts to double-spend. The only way to confirm the absence of a transaction is to be aware of all transactions. In the mint based model, the mint was aware of all transactions and decided which arrived first. To accomplish this without a trusted party, transactions must be publicly announced [1], and we need a system for participants to agree on a single history of the order in which they were received. The payee needs proof that at the time of each transaction, the majority of nodes agreed it was the first received.

3. Timestamp Server

The solution we propose begins with a timestamp server. A timestamp server works by taking a hash of a block of items to be timestamped and widely publishing the hash, such as in a newspaper or Usenet post [2-5]. The timestamp proves that the data must have existed at the time, obviously, in order to get into the hash. Each timestamp includes the previous timestamp in its hash, forming a chain, with each additional timestamp reinforcing the ones before it.

4. Proof-of-Work

To implement a distributed timestamp server on a peer-to-peer basis, we will need to use a proofof-work system similar to Adam Back's Hashcash [6], rather than newspaper or Usenet posts. The proof-of-work involves scanning for a value that when hashed, such as with SHA-256, the hash begins with a number of zero bits. The average work required is exponential in the number of zero bits required and can be verified by executing a single hash.

For our timestamp network, we implement the proof-of-work by incrementing a nonce in the block until a value is found that gives the block's hash the required zero bits. Once the CPU effort has been expended to make it satisfy the proof-of-work, the block cannot be changed without redoing the work. As later blocks are chained after it, the work to change the block would include redoing all the blocks after it.

The proof-of-work also solves the problem of determining representation in majority decision making. If the majority were based on one-IP-address-one-vote, it could be subverted by anyone able to allocate many IPs. Proof-of-work is essentially one-CPU-one-vote. The majority decision is represented by the longest chain, which has the greatest proof-of-work effort invested in it. If a majority of CPU power is controlled by honest nodes, the honest chain will grow the fastest and outpace any competing chains. To modify a past block, an attacker would have to redo the proof-of-work of the block and all blocks after it and then catch up with and surpass the work of the honest nodes. We will show later that the probability of a slower attacker catching up diminishes exponentially as subsequent blocks are added.

To compensate for increasing hardware speed and varying interest in running nodes over time, the proof-of-work difficulty is determined by a moving average targeting an average number of blocks per hour. If they're generated too fast, the difficulty increases.

5. Network

The steps to run the network are as follows:

- 1) New transactions are broadcast to all nodes.
- 2) Each node collects new transactions into a block.
- 3) Each node works on finding a difficult proof-of-work for its block.
- 4) When a node finds a proof-of-work, it broadcasts the block to all nodes.
- 5) Nodes accept the block only if all transactions in it are valid and not already spent.
- 6) Nodes express their acceptance of the block by working on creating the next block in the chain, using the hash of the accepted block as the previous hash.

Nodes always consider the longest chain to be the correct one and will keep working on extending it. If two nodes broadcast different versions of the next block simultaneously, some nodes may receive one or the other first. In that case, they work on the first one they received, but save the other branch in case it becomes longer. The tie will be broken when the next proof- of-work is found and one branch becomes longer; the nodes that were working on the other branch will then switch to the longer one.

New transaction broadcasts do not necessarily need to reach all nodes. As long as they reach many nodes, they will get into a block before long. Block broadcasts are also tolerant of dropped messages. If a node does not receive a block, it will request it when it receives the next block and realizes it missed one.

6. Incentive

By convention, the first transaction in a block is a special transaction that starts a new coin owned by the creator of the block. This adds an incentive for nodes to support the network, and provides a way to initially distribute coins into circulation, since there is no central authority to issue them. The steady addition of a constant of amount of new coins is analogous to gold miners expending resources to add gold to circulation. In our case, it is CPU time and electricity that is expended.

The incentive can also be funded with transaction fees. If the output value of a transaction is less than its input value, the difference is a transaction fee that is added to the incentive value of the block containing the transaction. Once a predetermined number of coins have entered circulation, the incentive can transition entirely to transaction fees and be completely inflation free.

The incentive may help encourage nodes to stay honest. If a greedy attacker is able to assemble more CPU power than all the honest nodes, he would have to choose between using it to defraud people by stealing back his payments, or using it to generate new coins. He ought to find it more profitable to play by the rules, such rules that favour him with more new coins than everyone else combined, than to undermine the system and the validity of his own wealth.

7. Reclaiming Disk Space

Once the latest transaction in a coin is buried under enough blocks, the spent transactions before it can be discarded to save disk space. To facilitate this without breaking the block's hash, transactions are hashed in a Merkle Tree [7][2][5], with only the root included in the block's hash. Old blocks can then be compacted by stubbing off branches of the tree. The interior hashes do not need to be stored.

A block header with no transactions would be about 80 bytes. If we suppose blocks are generated every 10 minutes, 80 bytes * 6 * 24 * 365 = 4.2MB per year. With computer systems typically selling with 2GB of RAM as of 2008, and Moore's Law predicting current growth of 1.2GB per year, storage should not be a problem even if the block headers must be kept in memory.

8. Simplified Payment Verification

It is possible to verify payments without running a full network node. A user only needs to keep a copy of the block headers of the longest proof-of-work chain, which he can get by querying network nodes until he's convinced he has the longest chain, and obtain the Merkle branch linking the transaction to the block it's timestamped in. He can't check the transaction for himself, but by linking it to a place in the chain, he can see that a network node has accepted it, and blocks added after it further confirm the network has accepted it.

As such, the verification is reliable as long as honest nodes control the network, but is more vulnerable if the network is overpowered by an attacker. While network nodes can verify transactions for themselves, the simplified method can be fooled by an attacker's fabricated transactions for as long as the attacker can continue to overpower the network. One strategy to protect against this would be to accept alerts from network nodes when they detect an invalid block, prompting the user's software to download the full block and alerted transactions to confirm the inconsistency. Businesses that receive frequent payments will probably still want to run their own nodes for more independent security and quicker verification.

9. Combining and Splitting Value

Although it would be possible to handle coins individually, it would be unwieldy to make a separate transaction for every cent in a transfer. To allow value to be split and combined, transactions contain multiple inputs and outputs. Normally there will be either a single input from a larger previous transaction or multiple inputs combining smaller amounts, and at most two outputs: one for the payment, and one returning the change, if any, back to the sender.

It should be noted that fan-out, where a transaction depends on several transactions, and those transactions depend on many more, is not a problem here. There is never the need to extract a complete standalone copy of a transaction's history.

10. Privacy

The traditional banking model achieves a level of privacy by limiting access to information to the parties involved and the trusted third party. The necessity to announce all transactions publicly precludes this method, but privacy can still be maintained by breaking the flow of information in another place: by keeping public keys anonymous. The public can see that someone is sending an amount to someone else, but without information linking the transaction to anyone. This is similar to the level of information released by stock exchanges, where the time and size of individual trades, the "tape", is made public, but without telling who the parties were.

As an additional firewall, a new key pair should be used for each transaction to keep them from being linked to a common owner. Some linking is still unavoidable with multi-input transactions, which necessarily reveal that their inputs were owned by the same owner. The risk is that if the owner of a key is revealed, linking could reveal other transactions that belonged to the same owner.

11. Calculations

We consider the scenario of an attacker trying to generate an alternate chain faster than the honest chain. Even if this is accomplished, it does not throw the system open to arbitrary changes, such as creating value out of thin air or taking money that never belonged to the attacker. Nodes are not going to accept an invalid transaction as payment, and honest nodes will never accept a block containing them. An attacker can only try to change one of his own transactions to take back money he recently spent.

The race between the honest chain and an attacker chain can be characterized as a Binomial Random Walk. The success event is the honest chain being extended by one block, increasing its lead by +1, and the failure event is the attacker's chain being extended by one block, reducing the gap by -1.

The probability of an attacker catching up from a given deficit is analogous to a Gambler's Ruin problem. Suppose a gambler with unlimited credit starts at a deficit and plays potentially an infinite number of trials to try to reach breakeven. We can calculate the probability he ever reaches breakeven, or that an attacker ever catches up with the honest chain, as follows [8]:

p = probability an honest node finds the next block q = probability the attacker finds the next block $q_z =$ probability the attacker will ever catch up from z blocks behind

 $q_{z} = \begin{cases} 1 & ifp \le q \\ q/p^{z} & ifp \le q \end{cases}$

Given our assumption that p > q, the probability drops exponentially as the number of blocks the attacker has to catch up with increases. With the odds against him, if he doesn't make a lucky lunge forward early on, his chances become vanishingly small as he falls further behind.

We now consider how long the recipient of a new transaction needs to wait before being sufficiently certain the sender can't change the transaction. We assume the sender is an attacker who wants to make the recipient believe he paid him for a while, then switch it to pay back to himself after some time has passed. The receiver will be alerted when that happens, but the sender hopes it will be too late.

The receiver generates a new key pair and gives the public key to the sender shortly before signing. This prevents the sender from preparing a chain of blocks ahead of time by working on it continuously until he is lucky enough to get far enough ahead, then executing the transaction at that moment. Once the transaction is sent, the dishonest sender starts working in secret on a parallel chain containing an alternate version of his transaction.

The recipient waits until the transaction has been added to a block and z blocks have been linked after it. He doesn't know the exact amount of progress the attacker has made, but assuming the honest blocks took the average expected time per block, the attacker's potential progress will be a Poisson distribution with expected value:

$$\bigoplus z \frac{q}{p}$$

To get the probability the attacker could still catch up now, we multiply the Poisson density for each amount of progress he could have made by the probability he could catch up from that point:

$$\sum_{k=0}^{\infty} \frac{\underline{\bigcirc}^{k} \bar{e}^{\textcircled{\scriptsize \bigcirc}}}{k!} \left\{ q/p \quad \begin{array}{c} z^{-k} & \text{if } k \leq z \\ 1 & \text{if } k < z \end{array} \right\}$$

Rearranging to avoid summing the infinite tail of the distribution

$$1 - \sum_{k=0}^{z} \frac{\bigoplus e^{-\Theta}}{k!} 1 - q/p \quad z = k$$

Converting to C code ...

```
#include <math.h>
double AttackerSuccessProbability(double q, int z)
{
    double p = 1.0 - q;
    double lambda = z * (q / p);
    double sum = 1.0;
    int i, k;
    for (k = 0; k <= z; k++)
    {
        double poisson = exp(-lambda);
        for (i = 1; i <= k; i++)
            poisson *= lambda / i;
        sum -= poisson * (l - pow(q / p, z - k));
    }
    return sum;
}</pre>
```

Running some results, we can see the probability drop off exponentially with z.

We have proposed a system for electronic transactions without relying on trust. We started with the usual framework of coins made from digital signatures, which provides strong control of ownership, but is incomplete without a way to prevent double-spending. To solve this, we proposed a peer-to-peer network using proof-of-work to record a public history of transactions that quickly becomes computationally impractical for an attacker to change if honest nodes control a majority of CPU power. The network is robust in its unstructured simplicity. Nodes work all at once with little coordination. They do not need to be identified, since messages are not routed to any particular place and only need to be delivered on a best effort basis. Nodes can leave and rejoin the network at will, accepting the proof-of-work chain as proof of what happened while they were gone. They vote with their CPU power, expressing their acceptance of valid blocks by working on extending them and rejecting invalid blocks by refusing to work on them. Any needed rules and incentives can be enforced with this consensus mechanism.

Vladimir Putin and Vitalik Buterin Discuss Ethereum 'Opportunities'

Jun 5, 2017 at 17:31 UTC • Updated Jun 5, 2017 at 17:32 UTC

У f in

The president of Russia briefly met with ethereum inventor Vitalik Buterin during an event last week.

SMART CONTRACT

Transactions in bitcoin arelimited

- Transfer 'X' bitcoins from 'Y' to 'Z'
- More powerful transactions
 - Exchange
 - Auction
 - Games
 - Bets
 - Legal agreements
- Solution
 - Store smart contracts on the blockchain
 - Computer programs implement transactions
 - Immutability guarantees persistence

THE ETHEREUM

- A decentralized platform that runs **smart contracts**
- Proposed in late 2013 by Vitalik Buterin
- Released 2015
- Supports turning complete smart contracts (Solidity)
- A virtual machine for cryptocurrency (Ethereum Virtual Machine)
 - Creating new currencies
 - Guaranteeing certain currency consistency
- But has all bad features of computer programs (DAO, Parity, ...)

WHAT IS MINING?

Mining is a process in which transactions for various forms of <u>cryptocurrency</u> are verified and added to the <u>blockchain</u> digital ledger.

MINING & POW AND POS

PROOF OF WORK (PoW)

Proof-of-Work, or PoW, is the original consensus algorithm in a Blockchain network.

PROOF OF WORK (PoW)

In Blockchain, this algorithm is used to confirm transactions and produce new blocks to the chain.

K NI

PROOF OF WORK (PoW)

With PoW, miners compete against each other to complete transactions on the network and get rewarded.

PROOF OF STAKE (PoS)

Alternative

to PoW

PROOF OF STAKE (PoS)

Proof of Stake (PoS) gives mining power based on the percentage of coins held by a miner.

PROOF OF STAKE (PoS)

PoS is seen as less risky in terms of the potential for miners to attack the network.

WHAT IS WEB MINING?

Users can join the mining process and get rewarded solely with the help of their PC/ Laptop.

MINING COMMUNITY/ POOL

A **Mining pool** is the pooling of resources by **miners**, who share their processing power over a network, to split the reward equally, according to the amount of work they contributed to the probability of finding a block.

DIFFERENT METHODS OF MINING CRYPTOCURRENCIES

INTERNET BUSINESS IDEA 7/100

Monetizing The Affiliate Website Traffic For Web Mining Contract

STRATEGY 18/100

AFFILIATE WEB MINING

THINGS REQUIRED

E-WALLET/ CRYPTO WALLER

PUBLISHER ACCOUNT WITH AFFILIATE PROGRAM

Your Website Traffic Is Monetizing With Mining As Well.

TO MAKE MONEY FROM AFFILIATE PROGRAMS, HERE ARE THE STEPS

STEP 1: Create your own website

STEP 2: Apply for the affiliate program and wait for the merchant to approve your site.

Click here to visit Valerie and Griffin.

This link points to merchant's website. Payout is 20% for all products sold, except for which a specific percentage is defined (see the dropdown below).

INSTRUCTIONS

1. Right Click (PC) or CTRL+CLICK (MAC) in the code box. Left click on "Select All" in the right click context menu that comes up. 2. Right Click (PC) or CTRL+CLICK (MAC) in the code box. Left click on "Copy" in the right click context menu that comes up. 3. Open you webpage in an HTML/TEXT editor and paste the code. For MySpace, just paste the code in your profile.

STEP 3: After approval , login in to the website affiliate program section and copy out the codes for either banner or text links..

STEP 4:

Each affiliate is assigned an affiliate id and this id can be seen in part of the banner /text link codes . do not edit the codes , or else you will not be entitled for any commission.

STEP 5: Copy and paste the codes in to the source code of your website

It is quite difficult to handle the source code modification by a **Non-Technical** person!!!

Introducing Affiliate E-Store Platform, that has been designed in such a way that anyone with the basic knowledge of internet can operate and manage their store, without having to worry about the technicalities involved otherwise.

To simplify it further, a customised dashboard has been added to your estore to make its running and corresponding operations smooth and even more hassle free.

BASED ON BRAND

Adding product based on brand of your choice

Merchant is a company that drive traffic to their website or sales off their product through ads and links placed in affiliates.

- Verenanis

Merchants

Merchants will normally pay affiliates a commission for every visit to the website or every sales conversion.

Add multiple merchant APIs for a single product (Ten affiliate merchants).

Full Spectrum CBD Oil Tinctures

CBD OIL ~

ZERO HIGH[™] CBD PET CBD

THE BEST CBD AFFILIATE COMMISSION STRUCTURE AVAILABLE

Our CBD commission structure starts at 25% for Gold level affiliates. Your commissions increase as your cumulative monthly sales grow, with incentives as high as 35% per sale.

LIFETIME CUSTOMER COMMISSIONS

When a customer purchases a product through your referral, they'll be tracked under your account for life. That means you'll earn commissions on recurring sales, including automated recur billing packages they sign up for.

THREE TIER COMMISSION STRUCTURE

In addition to earning commissions for all direct sales you refer, you'll also earn 5% on customer sales from affiliates you refer and 2% on customer sales from affiliates referred by those affiliates!

SPECIAL OFFER

PAYMENTS TWICE PER MONTH

We know revenue is important for you to maintain day-to-day operations. That's why we pay our affiliates twice per month via convenient digital transfers directly to your Paypal account. (Check payment options also available)

45-DAY TRACKING COOKIES

Your referral will be tracked for 45 days, just in case a customer is not prepared to purchase on their first visit.

LOTS OF WAYS TO LINK TO US

We have numerous methods for linking to us so that you can promote our products on your website (direct domain tracking), social media (personalized reference links), videos (coupon codes for your viewers), podcasts, newsletters and anything else you can think of.

INSTANT ACCESS - START YOUR PROMOTIONS RIGHT AWAY

Use the registration link below to signup and we'll instantly approve your account
